You must place class files in a directory called Bedrock, make the parent directory...crea sibling directory to these two that is named `classes' (eg c:\jdk1.2.2\jre\classes), you can use it to hold bare *class* files that wi automatically be found by your running programs. Similarly, you can add a j. file to the directory c:\jdk1.2.2\jre\lib\ext, and it will be *searched* fo. packages and classes automatically. Second, you can also use the classes directory with packages. If you place several classes into a package named Bedrock, you can then place the bare *class* files into a subdirectory with same name beneath classes (eg c:\jdk1.2.2\jre\classes\Bedrock). Abstract: *Java* applications require multiple *class* files, but these files can experience installation problems. These problems can include classpath issues and *class* packaging incompatibilities. *Java* multiple *class* files also make it too easy for users to decompile and an application's classes. *Zip* Fries offer a solution to these problems, but *zip* files often req modifications to the classpath and the files are not encrypted. A custom encryption and packag system that is implemented as a self-extracting, Java-executable file offers a solution to these problems. The default *Java* *class* loader will look to the classpath to locate a class file, but class can override the default loader and control the location and loading...

Text:

Every nontrivial *Java* application requires multiple *class* files, but dewith them can be a pain. One problem with multiple class files, for instancinvolves installation. Installation of any software, not just...
...registry keys and sometimes additional environment variables. Java

applications are especially prone to classpath issues, and sometimes even conspactions are especially prone to classpath issues, and sometimes even conspaction incompatibilities, such as those between *zip* and cab files. A second problem with multiple *class* files is that *Java* makes it all to easy for users to decompile and reuse an application's classes. Each class create takes some measure of time and money. However, typical Java packagin methodologies allow others to steal your work.

One way to get around both problems is to create *zip* Fries. However *zip* files often require users to modify the classpath. Secondly, *zip* files not encrypted, so users can unzip Fries and decompile or use your class

The only real solution to both problems, therefore, is to build a cus encryption and packaging system and implement it as a self- extracting, Java-executable file. Even though the default *Java* *class* loader looks to class path to find a given class file, a class can override the default load and control how and where additional classes...

...such a way that the main class is distinct from supporting classes.

Invoking the main class is rather trivial. The application must first query the *class* via the *java*.lang.*Class*.getDeclaredMethod() method to the main method. This method takes two parameters, a string representing the method, and an array of parameters. To find the...method for the application use an encryption method.

The application is broken down into four phases: packaging, encryption/decryption, loading, and execution.

Packaging. The *class* packaging method is the method this application uses. The application simply builds a ByteArrayOutputStream object and write

the *class* bundle to the list (see Listing One). As the application works through the *class* list, it is able to switch between encryption methods be examining the *class* file list and *searching* for methods with a signature matching the Container *class*'s encrypt() method.

The DBBTree Classes

My Java code that reads Berkeley DB files consists of three classes. 'primary *class* (and currently the only public *class*) is DBBTree (Listing One). You create a DBBTree object by giving it a filename or File object. I opens the file, reads the metadata, and then provides access to the database through the *search*() method, which accepts a byte array with the desired and returns another byte array with the corresponding data.

A DBBTreePage *searches* itself using a simple binary *search*. It us the DBBTreeNode *class* to access particular nodes and compare them to the requested key. If the DBBTreePage is an internal page, it identifies the cochild page, asks the DBBTree object to fetch that page, then asks that page *search* itself. This process continues recursively until a leaf page *sear itself and either returns the desired data or returns a null value to indicatellure.

1 Equivalence analysis and its application in improving the efficiency of program slicing

Donglin Liang , Mary Jean Harrold

ACM Transactions on Software Engineering and Methodology (TOSEM) July 2002 Volume 11 Issue 3

Existing methods for handling pointer variables during dataflow analyses can make such analyses inefficient in both time and space because the data-flow analyses must store and propagate large sets of data facts that are introduced by dereferences of pointer variables. This article presents *equivalence analysis*, a general technique to improve the efficiency of data-flow analyses in the presence of pointer variables. The technique identifies equivalence relations among the memory locations ...

We explore how to organize large text databases hierarchically by topic to aid better searching, browsing and filtering. Many corpora, such as internet directories, digital libraries, and patent databases are manually organized into topic hierarchies, also called *taxonomies*. Similar to indices for relational data, taxonomies make search and access more efficient. However, the exponential growth in the volume of on-line textual information makes it nearly impossible to maintain such taxono ...

Materialized views can provide massive improvements in query processing time, especially for aggregation queries over large tables. To realize this potential, the query optimizer must know how and when to exploit materialized views. This paper presents a fast and scalable algorithm for determining whether part or all of a query can be computed from materialized views and describes how it can be incorporated in transformation-based optimizers. The current version handles views composed of sele ...

ACM SIGMIS Database June 1998

Volume 29 Issue 3

A database management system should support views to facilitate filtering of information in order to have only necessary and required information available to users with minimal delay. Although a lot of research efforts concentrated on views within the conventional relational model, much more effort is required when object-oriented models are considered. However, supporting views is only a step forward in achieving the purpose that requires improving the performance of the system by considering ...

This paper describes how to add first-class generic types---including mixins---to strongly-typed OO languages with nominal subtyping such as Java and C#. A generic type system is "first-class" if generic types can appear in any context where conventional types can appear. In this context, a mixin is simply a generic class that extends one of its type parameters, e.g., a class C<T> that extends T. Although mixins of this form are widely used in Cpp (via templates), they are clumsy an ...

Determining the potential targets of virtual method invocations is essential for interprocedural optimizations of object-oriented programs. It is generally hard to determine such targets accurately. The problem is especially difficult for dynamic languages such as Java, because additional targets of virtual calls may appear at runtime. Current mechanisms that enable inter-procedural optimizations for dynamic languages, repeatedly validate the optimizations at runtime. This paper addresses this ...
